

# Recitation 4: Solutions for Exercise Problem

Shunkei Kakimoto

Let me know when you have any questions.

## Summer 2013 environment prelim

Two consumers are the only members of an island economy. They have identical preferences over two goods, a private numeraire good  $x$  and a pure public good  $q$ . Preferences are given by

$$U_i(x_i, q) = \ln x_i + 2 \ln q.$$

Each consumer is endowed with  $\omega_i = 10$  of the private good, of which  $x_i$  is consumed directly and the remainder  $z_i = \omega_i - x_i$  is contributed to the provision of the public good.  $q$  is produced according to the simple production function  $q = z_1 + z_2$ .

- Determine the outcome  $(x_1, x_2, z_1, z_2)$ , that a benevolent social planner would choose so as to maximize the unweighted sum of preferences,  $W = U_1(x_1, q) + U_2(x_2, q)$ .
- Find the voluntary-contribution equilibrium for this economy. Show that the VCE level of the public good,  $\hat{q}$  is less than  $q^*$ .
- Find the Lindahl price at which the consumers, taking this price as given when selecting their contribution  $z_i$ , will choose the socially optimal level of contribution to the public good.

## Solution

### Part a

The aggregate endowment is  $\omega = \omega_1 + \omega_2 = 20$ . The social planner's problem is to allocate this endowment to  $x_1, x_2$ , and  $q$  so that the social welfare function  $W = U_1(x_1, q) + U_2(x_2, q) = \log x_1 + \log x_2 + 4 \log q$  is maximized:

$$\begin{aligned} \max_{x_1, x_2, q} \quad & W = \log x_1 + \log x_2 + 4 \log q \\ \text{s.t.} \quad & q = 20 - x_1 - x_2 \end{aligned}$$

Note that  $x_1 > 0$ ,  $x_2 > 0$ , and  $q > 0$  by the form of  $U_j$ . So we should have an interior solution.

$$L = \log x_1 + \log x_2 + 4 \log q + \lambda(20 - x_1 - x_2 - q)$$

F.O.Cs are

$$\frac{\partial L}{\partial x_1} = \frac{1}{x_1} - \lambda = 0 \quad \dots (1)$$

$$\frac{\partial L}{\partial x_2} = \frac{1}{x_2} - \lambda = 0 \quad \dots (2)$$

$$\frac{\partial L}{\partial q} = \frac{4}{q} - \lambda = 0 \quad \dots (3)$$

$$\frac{\partial L}{\partial \lambda} = 20 - x_1 - x_2 - q = 0 \quad \dots (4)$$

By the conditions (1) and (2),

$$x_2 = x_1$$

By the the conditions (1) and (3),

$$q = 4x_1$$

Substituting these for condition (4),

$$20 - x_1 - x_1 - 4x_1 = 0$$

Thus,  $x_1^{PO} = \frac{10}{3}$ . Then,  $x_2^{PO} = \frac{10}{3}$  and  $q^{PO} = \frac{40}{3}$ .

In summary, the socially optimum outcome is  $(x_1^{PO}, x_2^{PO}, z_1^{PO}, z_2^{PO}) = (\frac{10}{3}, \frac{10}{3}, \frac{20}{3}, \frac{20}{3})$ . The optimal level of public goods is  $q^{PO} = \frac{40}{3}$ .

## Part b

Consumer  $i$ 's ( $i \in 1, 2$ ) problem is

$$\begin{aligned} \max_{x_i, z_i} \quad & U_i = \log x_i + 2 \log q \\ \text{s.t.} \quad & x_i = 10 - z_i \\ & q = z_i + z_{-i} \end{aligned}$$

By incorporating the constraints into the objective function, this maximization problem becomes

$$\max_{z_i} \quad U_i = \log(10 - z_i) + 2 \log(z_i + z_{-i})$$

The first order condition for this unconstrained maximization problem is

$$-\frac{1}{10 - z_i} + \frac{2}{z_i + z_{-i}} = 0$$

or

$$z_i = \frac{20 - z_{-i}}{3}$$

(Note that this is person  $i$ 's response function to the other person's choice on contribution to the public goods.) This condition must hold for  $i = 1, 2$ . That is, the following must hold

$$z_1 = \frac{20 - z_2}{3}, z_2 = \frac{20 - z_1}{3}$$

By solving this equations simultaneously, we get  $z_1^{VCE} = z_2^{VCE} = 5$ . So,  $x_1^{VCE} = x_2^{VCE} = 10 - 5 = 5$ .

In summary, the VCE is  $(x_1^{VCE}, x_2^{VCE}, z_1^{VCE}, z_2^{VCE}) = (5, 5, 5, 5)$ , and  $q^{VCE} = z_1^{VCE} + z_2^{VCE} = 10$ , which is less than  $q^{PO}$  as expected.

### Part c

Let  $p_1$  and  $p_2$  be the Lindahl prices of the public good for consumer 1 and consumer 2. **Each consumer solves,**

$$\begin{aligned} \max_{x_i} \quad & U_i = \log x_i + 2 \log q \\ \text{s.t.} \quad & x_i + p_i q = 10 \end{aligned}$$

Again, the solution should be interior.

$$L = \log x_i + 2 \log q + \lambda(10 - x_i - p_i q)$$

F.O.Cs are

$$\begin{aligned} \frac{\partial L}{\partial x_i} &= \frac{1}{x_i} - \lambda = 0 \\ \frac{\partial L}{\partial q} &= \frac{2}{q} - \lambda p_i = 0 \\ \frac{\partial L}{\partial \lambda} &= 10 - x_i - p_i q \end{aligned}$$

From the first two conditions,

$$\begin{aligned} \frac{1}{x_i} &= \frac{1}{p_i} \cdot \frac{2}{q} \\ \iff q &= \frac{2}{p_i} x_i \quad \dots (*1) \end{aligned}$$

Substituting this for the last F.O.C.,

$$\begin{aligned} 10 - x_i + p_i \cdot \frac{2}{p_i} x_i &= 0 \\ \iff x_i &= \frac{10}{3} \end{aligned}$$

So, substituting this for condition (\*1), we have,

$$\begin{aligned} q &= \frac{2}{p_i} \cdot \frac{10}{3} \\ \iff p_i &= \frac{3}{20} q \quad \dots (*2) \quad (\text{for } i = 1, 2) \end{aligned}$$

**The producer's problem is**

$$\begin{aligned} \max_{q, z} \quad & p \cdot q - z \\ \text{s.t.} \quad & q = z \end{aligned}$$

, where  $p = p_1 + p_2$  and  $z = z_1 + z_2$ .

$$L = p \cdot q - z + \lambda(z - q)$$

F.O.C.

$$\begin{aligned} \frac{\partial L}{\partial q} &= p - \lambda = 0 \\ \frac{\partial L}{\partial z} &= -1 + \lambda = 0 \\ \frac{\partial L}{\partial \lambda} &= z - q = 0 \end{aligned}$$

From the first two conditions, we have  $p = 1$ , or  $p_1 + p_2 = 1$ . Together with condition (\*2),

$$\begin{aligned} \frac{3}{20}q + \frac{3}{20}q &= 1 \\ \iff q &= \frac{10}{3} \end{aligned}$$

Substituting this for condition (\*2), we have the Lindahl price

$$p_i = \frac{1}{2} \quad \text{for } i = 1, 2$$
